## NUMERICAL METHODS FOR POWER-LAW DIFFUSION PROBLEMS \*

1

IOANNIS TOULOPOULOS\*<sup>†</sup> AND THOMAS WICK\*<sup>‡</sup>

Abstract. In this paper, we consider numerical methods for nonlinear diffusion problems where the diffusion term follows a power law, e.g., *p*-Laplace type problems. In the first part, we present continuous higher order finite element discretizations for the model problem and we derive error estimates. In the second part, we discuss Newton iterative methods based on residualbased line search and error-oriented globalization, which are employed for the numerical solution of the produced nonlinear algebraic system. Thirdly, we formulate the original problem as a saddle point problem in the frame of augmented Lagrangian techniques and present two iterative methods for its solution. We conduct a systematic investigation of all solution algorithms. These algorithms are compared with respect to computational cost and their efficiency. Numerical results demonstrating the theoretical error estimates are also presented in five examples.

11 Key words. power-law diffusion problems, *p*-Laplace type problems, high order finite element discretizations, Newton 12 iterative methods, augmented Lagrangian techniques

1. Introduction. Second order elliptic problems with *p*-type gradient nonlinearities in the diffusion coefficient, that is  $(\varepsilon^2 + |\nabla u|^2)^{\frac{p-2}{2}}$ , with  $\varepsilon \ge 0$  and  $p \in (1, \infty)$ , are of special interest and are relevant in many practical applications, e.g., in aerodynamics, porous media, non-Newtonian flows, plasticity and glaciology, and fluid-structure interaction [1, 2, 3, 4]. Therefore, the numerical solution of these problems is of great importance. In the application of numerical methods for solving these type of problems, we meet several difficulties associated mainly with the presence of the gradient in the *p*-nonlinear structure of the diffusion term.

The most classical *p*-type model problem that has been studied in the literature is the *p*-Laplace problem, 21 i.e.,  $\varepsilon = 0$ . The first analysis of finite element methods (FE) for p-Laplace was undertaken in [5] and in [6] 22 (chapter 5), where (sup-optimal) error estimates have been shown in the  $W^{1,p}$ -norm. These results were 23 further improved in [7] and recently, were used in [8, 9] for developing k and hk finite element methods, 24 where h denotes the spatial discretization parameter and k the degree of the polynomial space <sup>1</sup>. Recently, 25 optimal error bounds have been shown for *p*-Laplace and more general *p*-power law elliptic problems by using 26 quasi-norm interpolation estimates. The main idea in this approach is first to establish interpolation estimates 27 in a quasi-norm, which is predetermined by the *p*-nature of the problem, and then to derive error estimates 28 by exploiting the relations between the quasi- and Sobolev norms. Among others we quote [10, 11, 12, 13]. 29 In [14], interpolation operators in Orlicz-Sobolev spaces were studied and were utilized for approximating 30 solutions of more general *p*-type problems, the so-called *p*-structure problems. 31

Over the last two decades, there has been an increasing interest on devising discontinuous Galerkin (DG) methods for the numerical solution of *p*-type problems, see [15, 16, 17, 18]. In all these DG methods the numerical fluxes were developed by following the *p*-nonlinear nature of the problem. Particularly, in [16], local DG methods were studied for *p*-structure problems. The quasi-norm interpolation estimates presented in [14], were applied in the frame of broken paces and optimal error estimates were shown for linear elements. The same Local DG methods have been used later in [17] for solving more realistic *p*-type problems and in [19] for solving non-Newtonian flow problems.

We point out that the degenerate nature of the *p*-type problems makes the study of their regularity 39 properties quite difficult. In general we cannot guarantee high regularity for the solution u even with smooth 40 problem data, [20], and hence, the FE methods that have been applied for these problems usually consider first 41 order polynomial spaces. In [21], global  $W^{2,2}$  regularity properties were established under some assumptions 42 on the right hand side of the *p*-type model under consideration. These results were used in the discretization 43 error analysis in [21, 22]. Furthermore, it has been shown in [22] that under some further assumptions on 44 the problem data, we can obtain  $W^{1+2/p,p}$  regularity for the solutions of the p-Laplacian, and this regularity 45 is sufficient to ensure optimal error bounds. 46

<sup>47</sup> However, recently there has been much work on applying high-order tensor product spaces for solving <sup>48</sup> elliptic problems, even in cases with reduced regularity, and many techniques have been developed, e.g., <sup>49</sup> adaptive meshes, graded meshes, for recovering the optimal rates, see for example [8, 23, 24, 25, 26, 27]. In <sup>50</sup> this paper, motivated by the results in [14], we discuss high order interpolation error estimates in the same <sup>51</sup> quasi-norms for solving *p*-type diffusion problems, with  $p \in (1, \infty)$  and  $0 < \varepsilon \leq 1$ . <sup>2</sup>

<sup>&</sup>lt;sup>1</sup>In the literature, p usually denotes the degree of the polynomial space. Due to the appearance of the parameter p in the p-Laplace operator, we denote the polynomial degree by k.

<sup>&</sup>lt;sup>2</sup>We emphasize that in the numerical examples, we always use  $\varepsilon^2 > 0$ , which helps on relaxing the singular behavior of the

### I. Toulopoulos and T. Wick

In particular, assuming appropriate regularity properties for *u*, see Assumptions 2.1 and 2.3, we combine the structure (monotonicity) conditions presented in [14], with known high order interpolation estimates in Sobolev spaces, [28]. This helps us to derive quasi-norm interpolation error estimates using high order spaces. Having these estimates, we proceed and show optimal error bounds for sufficiently smooth solutions. We mention that in [14] quasi-norm error estimates have been shown for linear spaces but using a different methodology.

After the finite element discretization of the *p*-type diffusion problem we must solve a nonlinear algebraic system. In the second part of the paper, we present two Newton methods for solving the nonlinear algebraic system, (i) a classical residual-based procedure and (ii) an error-oriented approach, [29]. We also mention that in [30], inexact Newton methods with adaptive stopping criteria for the nonlinear and the linear solver have been presented. Therein, the stopping criteria is based on a posteriori error estimates, which split the global error into three parts, the discretization, the linearization and the algebraic part.

Initially inspired by the results in [31], we show bounds for the condition number of the iterative Newton 64 Jacobian matrix. Then we present two methods. The first method is simple to be materialized and uses 65 a classical criterion in order to check at each step whether the residual has been decreased. The second 66 method is based on a natural monotonicity criterion and rather than observing the residuals, two update 67 steps are compared. This second method is more expensive since an additional simplified problem needs to be 68 solved. Later, in the numerical examples, we investigate and compare the performance and the corresponding 69 convergence rates of the two Newton methods with respect to the variation of the problem parameters  $\varepsilon$  and 70 p. The comparisons are made in a wide range of problems with high and low regularity solutions. 71

Lastly, we treat the original problem by developing techniques which provide a separation of the gradient 72 of the solution from the nonlinearity. We achieve this by means of augmented Lagrangian (ALG) techniques. 73 The original problem is reformulated as a saddle point problem where the produced variational problem is 74 discretized by finite elements. We propose two iterative methods for solving the resulting nonlinear algebraic 75 system. The first iterative method is the classical ALG1 iterative method, which is usually used in the 76 literature, see a detailed analysis in [32]. It can be interpreted as a variant of the Uzawa algorithm, where 77 the Lagrange multiplier is separately updated after a sequence of nested iteration procedure and is denoted 78 by sALG1. The second proposed iterative method can be characterized as a monolithic approach, mALG1, 79 where all the unknown variables (state variable and Lagrange multiplier) are simultaneously computed in 80 one step. All proposed methods are compared with respect to computational cost and to the convergence 81 rates in several examples. We point out that both ALG1 methods yield the same numerical solutions (in 82 terms of accuracy) as the Newton methods. The mALG1 method is of optimal complexity and gives rise to a 83 more easy handling of the *p*-nonlinear nature of the model, but is not as fast as the Newton methods. To the 84 best of our knowledge, a comparison of these iterative techniques including also higher order finite elements 85 discretizations has not yet been presented in the existing literature. 86

The outline of the paper is as follows. In Section 2, the model problem is introduced. Furthermore, the FE discretization analysis to this problem is presented. In Section 3, residual-based and error-oriented Newton methods are formulated. Also, in the same section the solution of the problem under the augmented Lagrangian methodology is presented and the two ALG1 iterative methods are in details described. Finally, in Section 4 systematic comparisons of all solution algorithms in terms of convergence rates, Newton iterations, and CPU times are measured. We also present numerical results to confirm the theoretical error bounds. The paper closes with the conclusions in Section 5.

**2.** The model problem. Let  $\Omega$  be a bounded polygonal domain in  $\mathbb{R}^d$ , with d = 2 and  $\Gamma_D = \partial \Omega$ . We consider the following scalar *p*-type problem

(2.1) 
$$-\operatorname{div} \mathbf{A}(\nabla u) = f \quad in \ \Omega, \qquad u = u_D \quad on \ \Gamma_D,$$

where  $f: \Omega \to \mathbb{R}$  and  $u_D: \Gamma_D \to \mathbb{R}$  are given smooth functions. The operator  $\mathbf{A}(\nabla u): \mathbb{R}^2 \to \mathbb{R}^2$  has the following *p*-power law form

(2.2) 
$$\mathbf{A}(\nabla u) = (\varepsilon^2 + |\nabla u|^2)^{\frac{p-2}{2}} \nabla u,$$

where  $p \in (1, \infty)$  and  $\varepsilon > 0$  are model parameters and  $|\cdot|^2 = (\cdot, \cdot)$ . The function  $a(\nabla u) = (\varepsilon^2 + |\nabla u|^2)^{\frac{p-2}{2}}$  is the diffusivity term of (2.1). As we can observe by (2.2), the nonlinear nature of the problem is due to the appearance of  $|\nabla u|$  in the diffusivity function and this poses numerical challenges. We introduce the closely related function  $\mathbf{F} : \mathbb{R}^2 \to \mathbb{R}^2$  to the operator  $\mathbf{A}$  by

(2.3) 
$$\mathbf{F}(\mathbf{a}) = (\varepsilon^2 + |\mathbf{a}|^2)^{\frac{p-2}{4}} \mathbf{a}.$$

problem at points where  $|\nabla u| = 0$ . However, we perform numerical tests setting  $\varepsilon^2 = 10^{-8}$ , which can give us an idea about the behavior of the algorithm for the classical *p*-Laplace problem.

**2.1. Preliminaries and notation.** Let  $1 \leq p \leq \infty$  be fixed and l be a non-negative integer. As usual,  $L^p(\Omega)$  denotes Lebesgue spaces for which  $\int_{\Omega} |u(x)|^p dx < \infty$ , endowed with the norm  $||u||_{L^p(\Omega)} = (\int_{\Omega} |u(x)|^p dx)^{\frac{1}{p}}$ , and  $W^{l,p}(\Omega)$  is the Sobolev space, which consists of the functions  $\phi : \Omega \to \mathbb{R}$  such that their weak derivatives  $D^{\alpha}\phi$  with  $|\alpha| \leq l$  belong to  $L^p(\Omega)$ . If  $\phi \in W^{l,p}(\Omega)$ , then its norm is defined by

$$\|\phi\|_{W^{l,p}(\Omega)} = \Big(\sum_{0 \le |\alpha| \le l} \|D^{\alpha}\phi\|_{L^{p}(\Omega)}^{p}\Big)^{\frac{1}{p}} \quad \text{and} \quad \|\phi\|_{W^{l,\infty}(\Omega)} = \max_{0 \le |\alpha| \le l} \|D^{\alpha}\phi\|_{L^{\infty}(\Omega)},$$

for  $1 \le p < \infty$  and  $p = \infty$ , respectively. We refer the reader to [33] for more details about Sobolev spaces. Furthermore, we define the spaces

(2.4) 
$$W_D^{l,p} := \{ u \in W^{l,p}(\Omega) : u |_{\partial\Omega} = u_D \}, \text{ and } W_0^{l,p} := \{ u \in W^{l,p}(\Omega) : u |_{\partial\Omega} = 0 \}.$$

In what follows, positive constants c and C appearing in the inequalities are generic constants which do not depend on the mesh-size h. We indicate on what may the constants depend for a better understanding of the proofs. Frequently, we will write  $a \sim b$  meaning that  $ca \leq b \leq Ca$ , with c and C independent of the mesh size.

**2.2.** The weak problem . The weak formulation for (2.1) reads as follows: Find  $u \in W_D^{1,p}$  such that

(2.5a) 
$$B(u,\phi) = l_f(\phi), \ \forall \phi \in W_0^{1,p}(\Omega), \text{ where } B(u,\phi) = \int_{\Omega} \mathbf{A}(\nabla u) \cdot \nabla \phi \, dx, \text{ and } l_f(\phi) = \int_{\Omega} f \phi \, dx.$$

Depending on the form of **A** and on the range of p, the well-posedness has been examined by means of monotone operators in several works, see e.g., [6, 7].

Problem (2.5) is equivalent to the minimization problem:

(2.6) Find 
$$u \in W_D^{1,p}$$
 such that  $J(u) \le J(\phi), \ \forall \phi \in W_D^{1,p}$ 

where  $J: W_D^{1,p} \to \mathbb{R}$  is defined by

(2.7) 
$$J(\phi) = \frac{1}{p} \int_{\Omega} (\varepsilon^2 + |\nabla \phi|^2)^{\frac{p}{2}} dx - \int_{\Omega} f \phi \, dx$$

Furthermore, one can show that the Gateaux derivative of B is given by

(2.8) 
$$B'(u)(v,w) = \int_{\Omega} (\varepsilon^2 + |\nabla u|^2)^{\frac{p-2}{2}} \nabla v \cdot \nabla w \, dx$$
$$+ (p-2) \int_{\Omega} (\varepsilon^2 + |\nabla u|^2)^{\frac{p-4}{2}} (\nabla u \cdot \nabla v) (\nabla u \cdot \nabla w) \, dx, \quad \text{for} \quad u, v, w \in W_D^{1,p}.$$

ASSUMPTION 2.1. Let  $l \geq 2$  be an integer and let  $p \in (1, \infty)$  and d = 2. We assume that the solution uof (2.5) belongs to  $V := W_D^{l,p}(\Omega)$ , where either (l-1)p > d and p > 1 or (l-1)p < d and  $p > \frac{2d}{d+1}$ . Further, we assume that  $\nabla \mathbf{F}(\nabla u) \in L^2(\Omega)$ . For simplicity, we assume the following for the boundary data:

ASSUMPTION 2.2. Let  $u_D \in \mathbb{P}^k(\Gamma_D)$ , where  $\mathbb{P}^k$  is the space of polynomials degree less than or equal to k. Further, we assume that  $|\int_{\Gamma_D} u_D ds| = 0$ .

**2.3. Known inequalities.** The following inequalities are going to be used in several places in the text. Hölder's and Young's inequalities read: For any  $\epsilon$ ,  $0 < \epsilon < \infty$ , and  $1 < p, q < \infty$  such that  $\frac{1}{p} + \frac{1}{q} = 1$ , for  $u \in L^{p}(\Omega)$  and  $v \in L^{q}(\Omega)$ , there holds

(2.9a) 
$$\left| \int_{\Omega} uv \, dx \right| \le \|u\|_{L^p(\Omega)} \|v\|_{L^q(\Omega)}, \qquad \left| \int_{\Omega} uv \, dx \right| \le \frac{\epsilon}{p} \|u\|_{L^p(\Omega)}^p + \frac{\epsilon^{-\frac{q}{p}}}{q} \|v\|_{L^q(\Omega)}^q.$$

Poincaré-Friedrichs inequality, see [28]: for any  $u \in W^{1,2}(\Omega)$ , it holds

(2.9b) 
$$\|u\|_{L^{2}(\Omega)} \leq C(\Omega, \partial\Omega) \Big( \|\nabla u\|_{L^{2}(\Omega)} + \big| \int_{\partial\Omega} u \, ds \big| \Big)$$

Next, we introduce some functions which will be useful to the following. For p > 1 and  $\varepsilon > 0$ , we define the functions

(2.10) 
$$\widehat{\varphi}(t) := (\varepsilon + t)^{p-2}$$

(2.11) 
$$\varphi(t) := \int_0^t (\varepsilon^2 + s^2)^{\frac{p-2}{2}} s \, ds,$$
 and it follows  $\varphi'(t) = (\varepsilon^2 + t^2)^{\frac{p-2}{2}} t.$ 

 $\sim \widehat{\varphi}(|\mathbf{P}| + |\mathbf{Q}|)|\mathbf{P} - \mathbf{Q}|^2,$ 

- <sup>107</sup> By an easy computation we can show that  $\varphi'(t) \sim t\varphi''(t)$  and  $\varphi''(t) \sim \widehat{\varphi}(t)$ . LEMMA 2.1. Let **A** be given by (2.2) and let **F** be defined by (2.3). Then the relations
  - (2.12a)  $(\mathbf{A}(\mathbf{P}) \mathbf{A}(\mathbf{Q})) \cdot (\mathbf{P} \mathbf{Q}) \sim |\mathbf{F}(\mathbf{P}) \mathbf{F}(\mathbf{Q})|^2,$

(2.12b)

(2.12c)  $|\mathbf{A}(\mathbf{P}) - \mathbf{A}(\mathbf{Q})| \sim \widehat{\varphi}(|\mathbf{P}| + |\mathbf{Q}|)|\mathbf{P} - \mathbf{Q}|,$ 

108 holds for all  $\mathbf{P}, \mathbf{Q} \in \mathbb{R}^2$ .

<sup>109</sup> *Proof.* The proofs are given in [34].  $\Box$ 

**2.4. Finite element notation.** Let  $T_h = \{E_i\}_{i=1}^{N_E}$  be a quasi-uniform subdivision of  $\Omega$  into quadrilateral elements (without hanging nodes) with the following properties: (i)  $\overline{\Omega} = \bigcup_{i=1}^{N_E} \overline{E_i}$ , (ii) if  $E_i$ ,  $E_j \in T_h$  then their closures are either disjoint, or have common vertex, or have common edge. As usual, we set  $h_{E_i}$  to be the diameter of  $E_i \in T_h$  and the mesh size h is considered to be the maximum diameter of  $E_i \in T_h$ , i.e.,  $h := \max_{E_i \in T_h} h_{E_i}$ .

Let  $E \in T_h$  and  $k \in \mathbb{N}$ , we denote  $\mathbb{Q}_k(E)$  the space of tensor product polynomials on E of degree less than or equal to k in each variable. On  $T_h$ , we define the approximation spaces  $V_{D,h}^{(k)} \subset V$ ,  $V_{0,h}^{(k)}$  and  $V_h^{(k)}$  as

(2.13a)  $V_{D,h}^{(k)} := \{ \phi_h \in C(\overline{\Omega}) : \phi_h |_E \in \mathbb{Q}_k(E), \forall E \in T_h, \text{ and } \phi_h |_{\partial\Omega} = u_D \},$ 

(2.13b) 
$$V_{0,h}^{(k)} := \{ \phi_h \in C(\overline{\Omega}) : \phi_h |_E \in \mathbb{Q}_k(E), \forall E \in T_h, \text{ and } \phi_h |_{\partial\Omega} = 0 \},$$

(2.13c) 
$$V_h^{(k)} := \{ \phi_h \in C(\overline{\Omega}) : \phi_h |_E \in \mathbb{Q}_k(E), \ \forall E \in T_h \}.$$

LEMMA 2.2. Let  $\mathcal{I}_h^k$  be the corresponding global interpolation operator and let  $u \in W^{l,p}(\Omega)$  with  $k+1 \ge l \ge 2$  and p > 1. Then, there exists a constant  $C_{intp} > 0$  independent of h such that, the interpolation estimate

$$(2.14) |u - \mathcal{I}_h^k u|_{W^{s,p}(\Omega)} \le C_{intp} h^{l-s} |u|_{W^{l,p}(\Omega)},$$

115 holds for  $0 \leq s \leq l$ .

<sup>116</sup> *Proof.* The proof can be found in [28].  $\Box$ 

REMARK 2.1. We present the error analysis for the spaces in (2.13) defined on quadrilateral elements, because these spaces are available in the software package deal.II [35, 36], which we use for performing the numerical tests. The same analysis can be applied for other spaces defined on other mesh elements, e.g. triangular elements.

<sup>121</sup> We proceed to the discretization analysis under the following assumption

ASSUMPTION 2.3. Let  $1 , <math>q = \frac{p}{p-1}$  and let  $\tau = \varepsilon + |\nabla u| + |\nabla \mathcal{I}_h^k u|$ . We assume  $\frac{1}{\tau} \in L^q(\Omega)$ .

REMARK 2.2. Note that, if  $\tau \geq 1$ , i.e.,  $\varepsilon = 1$ , we have  $\|\frac{1}{\tau}\|_{L^q(\Omega)} \leq \|\tau\|_{L^q(\Omega)}$ . Now, we can mention two cases. If  $u \in W^{l,p}$  with l = 2 and  $2 > p > \frac{2d}{d+1}$ , (for the d = 2 case that we study here, this means  $2 > p > \frac{4}{3}$ ), then using the Sobolev inequality  $\|u\|_{L^q(\Omega)} \leq \|u\|_{W^{1,p}(\Omega)}$ , it is easy to see that the Assumption 2.3 is fulfilled. Furthermore, if  $u \in W^{l,p}$  with l > 2 and (l-1)p - d > 0, then again using the Sobolev inequality  $\|u\|_{L^q(\Omega)} \leq \|u\|_{W^{1,p}(\Omega)}$ , we can see that the Assumption 2.3 is fulfilled.

In the analysis below, we will use some special cases of Sobolev embeddings theorem, see [33]. Let  $\hat{E}$  be the reference element, for example the unit square, and let  $\hat{u} \in W^{1+m,p}(\hat{E})$  with the integer  $m \ge 1$  and 2 > p > 1 such that: either mp > d and p > 1 or mp < d and  $p > \frac{2d}{d+1}$ , (i.e., for the d = 2, we have mp > 2 and p > 1 or mp < 2 and p > 1 or mp < 2 and  $p > \frac{4}{3}$ ). Then for q > p, it holds that

(2.15) 
$$\|\hat{u}\|_{W^{1,q}(\hat{E})} \le C \|\hat{u}\|_{W^{1+m,p}(\hat{E})},$$

where the constant C depends on d, p, q, m and  $\hat{E}$ . By the Sobolev embedding (2.15) we can derive that

(2.16) 
$$\|\hat{u}\|_{W^{1,q}(\hat{E})} \le C \left( \|\hat{u}\|_{L^{p}(\hat{E})}^{p} + |\hat{u}|_{W^{1,p}(\hat{E})}^{p} + |\hat{u}|_{W^{2,p}(\hat{E})}^{p} \right)^{\frac{1}{p}}.$$

Let  $E \in T_h$  and let  $T_E$  be the unique affine transformation that maps the reference element  $\hat{E}$  to  $E \in T_h$ ,

(2.17) 
$$T_E: \hat{E} \to E, \text{ with } T_E(\hat{x}) = B\hat{x} + b,$$

where |det(B)| = |E|. By applying a change of variables and using scaling arguments, we can show that

(2.18) 
$$|\hat{u}|_{W^{j,p}(\hat{E})} = h^{j-\frac{d}{p}} |u|_{W^{j,p}(E)}, \text{ for } 0 \le j \le l.$$

Finally, using (2.18) into (2.16), a simple computation yields that

(2.19) 
$$|u|_{W^{1,q}(E)}^2 \le Ch^{2(\frac{d}{q} - \frac{d}{p} - 1)} \left( ||u||_{L^p(E)}^p + h^p |u|_{W^{1,p}(E)}^p + h^{2p} |u|_{W^{2,p}(E)}^p \right)^{\frac{2}{p}}.$$

COROLLARY 2.3. Let  $u \in W^{1,q}(\Omega) \cap W^{l,p}(\Omega)$  with  $q > p, l \geq 2$ , and let  $\mathcal{I}_h^k$  be the corresponding interpolation. Then by (2.14) and (2.19), it follows that

(2.20) 
$$|u - \mathcal{I}_h^k u|_{W^{1,q}(E)}^2 \le Ch^{2(\frac{d}{q} - \frac{d}{p} - 1)} h^{2l} ||u||_{W^{2,p}(E)}^2.$$

128

LEMMA 2.4. Let **A** be given by (2.2) and let **F** be defined by (2.3). For  $\delta > 0$ , there exist a constant  $c(\delta)$ , such that for  $u, v, w \in V$  the following relation holds

$$(2.21) \quad \int_{\Omega} \left( \mathbf{A}(\nabla u) - \mathbf{A}(\nabla v) \right) \cdot \left( \nabla w - \nabla v \right) dx \le \delta \int_{\Omega} |\mathbf{F}(\nabla u) - \mathbf{F}(\nabla v)|^2 dx + c(\delta) \int_{\Omega} |\mathbf{F}(\nabla w) - \mathbf{F}(\nabla v)|^2 dx.$$

129 130

*Proof.* The proof can be found in [14].  $\Box$ 

2.5. Finite element approximation and error bounds. In this paragraph, we present the finite element discretization of (2.5). We develop our analysis inspired by the results in [14]. The finite element approximation of (2.5) reads as follows: find  $u_h \in V_{D,h}^{(k)}$  such that for all  $\phi_h \in V_{0,h}^{(k)}$  holds

$$(2.22) B(u_h,\phi_h) = l_f(\phi_h)$$

**PROPOSITION 2.5.** 131

(i) Let  $\{a_i\}_{i=1}^N$  be a sequence of nonnegative numbers. If  $p < q < \infty$  then

(2.23) 
$$\left(\sum_{i=1}^{N} a_{i}^{p}\right)^{\frac{1}{p}} \leq N^{\frac{1}{p}-\frac{1}{q}} \left(\sum_{i=1}^{N} a_{i}^{q}\right)^{\frac{1}{q}}$$

(ii) Let  $1 and let <math>E \in T_h$ . If  $u \in L^q(E)$  then there exist a C depending on the quasi-uniformity properties of  $T_h$  such that

(2.24) 
$$\|u\|_{L^{p}(E)} \leq Ch^{d(\frac{1}{p} - \frac{1}{q})} \|u\|_{L^{q}(E)}.$$

(iii) Let  $\{a_i\}_{i=1}^N$  be a sequence of nonnegative numbers. If 1 then

(2.25) 
$$\left(\sum_{i=1}^{N} a_{i}^{q}\right)^{\frac{1}{q}} \leq \left(\sum_{i=1}^{N} a_{i}^{p}\right)^{\frac{1}{p}}$$

132

*Proof.* (i) Let  $p^* = \frac{q}{p} > 1$  and  $q^* = \frac{p^*}{p^* - 1} = \frac{q}{q - p}$  its conjugate exponent. Recalling (2.9a) for vectors, we have

(2.26) 
$$\left(\sum_{i=1}^{N} a_{i}^{p} 1\right) \leq \left(\sum_{i=1}^{N} a_{i}^{q}\right)^{\frac{p}{q}} \left(\sum_{i=1}^{N} 1\right)^{\frac{q-p}{q}}$$

(ii) Inequality (2.24) can be shown in the same way as inequality (2.23). 134

(iii) We observe that the function  $f(x) = (a_1^x + a_2^x + \dots + a_N^x)^{\frac{1}{x}}$  is decreasing for  $x \ge 1$ . Then inequality 135 (2.25) follows. 136

Π

Below we prove the basic interpolation estimates in the related quasi-norms. 137

THEOREM 2.6. Let u satisfies Assumptions 2.1 and 2.2 and let  $\mathcal{I}_h^k u$  be the corresponding interpolant as defined above. Then, there exist  $c \geq 0$  depending on  $\varepsilon$ ,  $|\nabla u|$ ,  $|\nabla \mathcal{I}_h^k u|$ , the constant in (2.14) and the constant in (2.19), but independent of the grid size h, such that the following estimate holds true

(2.27) 
$$\int_{\Omega} |\mathbf{F}(\nabla u) - \mathbf{F}(\nabla \mathcal{I}_h^k u)|^2 \, dx \le c \, h^{2(l-1)} \|u\|_{W^{l,p}(\Omega)}^2$$

Taking the  $\frac{1}{n}$ th root in (2.26), we obtain (2.23). 133

*Proof.* For simplicity in the formulas below, we introduce the notation  $\tau := \widehat{\varphi}(|\nabla u| + |\nabla \mathcal{I}_h^k u|)|^{\frac{1}{p-2}} = \varepsilon + |\nabla u| + |\nabla \mathcal{I}_h^k u|$ . By the relations (2.12), we conclude that

(2.28) 
$$\int_{\Omega} |\mathbf{F}(\nabla u) - \mathbf{F}(\nabla \mathcal{I}_{h}^{k}u)|^{2} dx \leq \int_{\Omega} \widehat{\varphi}(|\nabla u| + |\nabla \mathcal{I}_{h}^{k}u|) |\nabla u - \nabla \mathcal{I}_{h}^{k}u)|^{2} dx.$$

Let us first prove the required relation for p > 2. Applying (2.9a) in (2.28) and setting  $q = \frac{p}{2}$ , we obtain

$$(2.29) \qquad \int_{\Omega} |\mathbf{F}(\nabla u) - \mathbf{F}(\nabla \mathcal{I}_{h}^{k}u)|^{2} dx \leq c \Big(\int_{\Omega} |\nabla u - \nabla \mathcal{I}_{h}^{k}u|^{\frac{2p}{2}} dx\Big)^{\frac{2}{p}} \Big(\int_{\Omega} (\widehat{\varphi}(|\nabla u| + |\nabla \mathcal{I}_{h}^{k}u|)^{\frac{p}{p-2}} dx\Big)^{\frac{p-2}{p}} dx \Big)^{\frac{p-2}{p}} dx$$
$$\leq c |\nabla u - \nabla \mathcal{I}_{h}^{k}u|^{2}_{W^{1,p}(\Omega)} \|\tau\|^{p-2}_{L^{p}(\Omega)} \leq ch^{2(l-1)} \|\tau\|^{p-2}_{L^{p}(\Omega)},$$

where the interpolation estimate (2.14) has been used.

For the case p < 2 we proceed as follows. Let  $E \in T_h(\Omega)$  and let  $q^* = \frac{q}{2}$  and  $p^* = \frac{p}{2-p}$ . By relations (2.12), we can conclude that

(2.30) 
$$\int_{E} |\mathbf{F}(\nabla u) - \mathbf{F}(\nabla \mathcal{I}_{h}^{k}u)|^{2} dx \leq \int_{E} \widehat{\varphi}(|\nabla u| + |\nabla \mathcal{I}_{h}^{k}u|) |\nabla u - \nabla \mathcal{I}_{h}^{k}u)|^{2} dx$$

We apply (2.9a) in (2.30) and consequently (2.19), and obtain

$$(2.31) \quad \sum_{E} \int_{E} |\mathbf{F}(\nabla u) - \mathbf{F}(\nabla \mathcal{I}_{h}^{k}u)|^{2} dx \leq c \sum_{E} \left( \int_{E} |\nabla u - \nabla \mathcal{I}_{h}^{k}u|^{\frac{2q}{2}} dx \right)^{\frac{2}{q}} \left( \int_{E} \tau^{-p} dx \right)^{\frac{2-p}{p}}$$

$$\leq c \sum_{E} |u - \mathcal{I}_{h}^{k}u|^{2}_{W^{1,q}(E)} \left\| \frac{1}{\tau} \right\|^{2-p}_{L^{p}(E)} \leq c \left( \sum_{E} |u - \mathcal{I}_{h}^{k}u|^{q}_{W^{1,q}(E)} \right)^{\frac{2}{q}} \left( \sum_{E} \left\| \frac{1}{\tau} \right\|^{p}_{L^{p}(E)} \right)^{\frac{2-p}{p}}$$

$$\leq c \left( \sum_{E} |u - \mathcal{I}_{h}^{k}u|^{2}_{W^{1,q}(E)} \right)^{\frac{2}{2}} \left( \sum_{E} \left\| \frac{1}{\tau} \right\|^{p}_{L^{p}(E)} \right)^{\frac{2}{p}} \left( \sum_{E} \left\| \frac{1}{\tau} \right\|^{p}_{L^{p}(E)} \right)^{-1}$$

$$\leq c h^{2\left(\frac{d}{q} - \frac{d}{p} - 1\right)} h^{2l} \|u\|^{2}_{W^{2,p}(\Omega)} h^{2d\left(\frac{1}{p} - \frac{1}{q}\right)} \left( \sum_{E} \left\| \frac{1}{\tau} \right\|^{p}_{L^{q}(E)} \right)^{\frac{2}{p}} \left( \left\| \frac{1}{\tau} \right\|^{p}_{L^{p}(\Omega)} \right)^{-1}$$

$$\leq c h^{2l-2} \|u\|^{2}_{W^{2,p}(\Omega)} \left( \sum_{E} \left\| \frac{1}{\tau} \right\|^{p}_{L^{q}(E)} \right)^{\frac{2}{p}} \left( \left\| \frac{1}{\tau} \right\|^{p}_{L^{p}(\Omega)} \right)^{-1}$$

where the interpolation estimate (2.14) and inequalities in Proposition 2.5 have been used. Finally, putting together the results (2.29) and (2.31), we have that

(2.32) 
$$\int_{\Omega} |\mathbf{F}(\nabla u) - \mathbf{F}(\nabla \mathcal{I}_{h}^{k}u)|^{2} dx \leq c h^{2l-2} \|u\|_{W^{l,p}(\Omega)}^{2}.$$

 $_{141}$   $\,$  This proves the theorem.  $\Box$ 

142

143

Let us now use the previous results for showing an estimate for the approximation error  $u_h - u$ .

THEOREM 2.7. Let  $u \in V$  be the solution of (2.5) under the Assumption 2.1, and let  $u_h \in V_{D,h}^{(k)}$  be the solution of (2.22). Then, there exist  $C \geq 0$  depending on the constant in (2.27) but independent of the grid size h, such that

(2.33) 
$$\int_{\Omega} |\mathbf{F}(\nabla u) - \mathbf{F}(\nabla u_h)|^2 \, dx \le Ch^{2(l-1)} \|u\|_{W^{l,p}(\Omega)}^2.$$

*Proof.* Let  $\phi_h \in V_{0,h}^{(k)}$  and let  $\mathcal{I}_h^k u \in V_{D,h}^{(k)}$  be the interpolant of u. By forms (2.5) and (2.22), we can deduce that

(2.34) 
$$\int_{\Omega} \left( \mathbf{A}(\nabla u) - \mathbf{A}(\nabla u_h) \right) \cdot \nabla \phi_h \, dx = 0.$$

where it follows that

(2.35) 
$$\int_{\Omega} \left( \mathbf{A}(\nabla u_h) - \mathbf{A}(\nabla \mathcal{I}_h^k u) \right) \cdot \nabla \phi_h \, dx = \int_{\Omega} \left( \mathbf{A}(\nabla u) - \mathbf{A}(\nabla \mathcal{I}_h^k u) \right) \cdot \nabla \phi_h \, dx.$$

Now, choosing  $\phi_h = u_h - \mathcal{I}_h^k u$  and  $\delta > 0$  small enough, relations (2.12) and inequality (2.21) imply that

(2.36) 
$$\int_{\Omega} |\mathbf{F}(\nabla u_h) - \mathbf{F}(\nabla \mathcal{I}_h^k u)|^2 \, dx \le c(\delta) \int_{\Omega} |\mathbf{F}(\nabla u) - \mathbf{F}(\nabla \mathcal{I}_h^k u)|^2 \, dx$$

<sup>145</sup> where by triangle inequality it follows that

(2.37) 
$$\int_{\Omega} |\mathbf{F}(\nabla u_h) - \mathbf{F}(\nabla u)|^2 \, dx \le c(\delta) \int_{\Omega} |\mathbf{F}(\nabla u) - \mathbf{F}(\nabla \mathcal{I}_h^k u)|^2 \, dx.$$

The desired estimate (2.33) follows immediately by applying the interpolation estimate (2.27) on the right hand side of (2.37).  $\Box$ 

3. Nonlinear iterative processes. In this section, we design several iterative methods for solving 148 problem (2.22). All proposed schemes are based on Newton-type approaches. We begin with an inspection 149 of the behavior of the eigenvalues of the Jacobian matrix of  $\mathbf{A}$ , see (2.2), in order to get a prefigure about the 150 behavior of the corresponding Newton iterative matrix around the critical points. Then, in Section 3.3, two 151 Newton-type iterative methods, e.g., residual-based descent and error-oriented techniques, are formulated. In 152 Section 3.4, augmented Lagrangian-type techniques are employed in order to reformulate the problem (2.1)153 as a saddle point problem. We discretize this last problem using a classical finite element procedure and 154 solve the resulting nonlinear system by applying two iterative procedures. Our final goal is to investigate the 155 performance of all the aforementioned methods through the numerical examples. 156

**3.1. Preliminary considerations.** In view of the form of operator **A** in (2.2), we introduce the function  $\mathbf{A} \in C^1(\mathbb{R}^2, \mathbb{R}^2)$  defined by

(3.1) 
$$\mathbf{A}(\eta) = (\varepsilon^2 + \eta_1^2 + \eta_2^2)^{\frac{p-2}{2}}(\eta_1, \eta_2).$$

By an easy computation, we can show that

$$(3.2) J_{\mathbf{A}} = \begin{bmatrix} (\eta_1^2 + \eta_2^2 + \varepsilon^2)^{(p-4)/2} ((p-1)\eta_1^2 + \eta_2^2 + \varepsilon^2) & (p-2)\eta_1\eta_2(\eta_1^2 + \eta_2^2 + \varepsilon^2)^{(p-4)/2} \\ (p-2)\eta_1\eta_2(\eta_1^2 + \eta_2^2 + \varepsilon^2)^{(p-4)/2} & (\eta_1^2 + \eta_2^2 + \varepsilon^2)^{(p-4)/2} ((p-1)\eta_2^2 + \eta_1^2 + \varepsilon^2)) \end{bmatrix}$$

with the eigenvalues

(3.3a)  
(3.3b)  

$$\lambda_1 = (\varepsilon^2 + \eta_1^2 + \eta_2^2)^{(p-2)/2},$$
(3.3b)  

$$\lambda_2 = (\varepsilon^2 + \eta_1^2 + \eta_2^2)^{(p-4)/2} ((p-1)(\eta_1^2 + \eta_2^2) + \varepsilon^2).$$

The behavior of the eigenvalues of the Jacobian  $J_{\mathbf{A}} := \frac{\partial \mathbf{A}(\eta)}{\partial \eta}$  with respect to the parameters  $\varepsilon$  and p, outline the behavior of the eigenvalues of the corresponding Jacobian matrix, which appears in the Newton iterative 157 158 process. Namely, for the cases where the eigenvalues of  $J_{\mathbf{A}}$  are close to zero, we can expect that Jacobian 159 matrix of the Newton method to be singular or ill-conditioned. Note that the eigenvalues  $\lambda_i$ , i = 1, 2 in (3.3) 160 have a similar form as the function  $\hat{\varphi}$  defined in (2.10). For example, if we set  $t = |\eta|$  then  $\lambda_i(t) \sim \hat{\varphi}(t)$ , i = 1, 2. Let  $r = (\eta_1, \eta_2)$  be the radial function with  $r^2 \leq 1$ . In Fig. 1, we plot  $\lambda_1$  and  $\lambda_2$  with respect to  $r^2 = \eta_1^2 + \eta_2^2$  for several values of  $\varepsilon$  and p. We observe that for p < 2 and  $\varepsilon < 1$  the values of both eigenvalues are getting very high as  $r^2 \to 0$  and the values are reduced as  $r^2 \to 1$ , see Figs 1(a),(b),(d),(e). Conversely for the case 161 162 163 164 where  $\varepsilon = 1$  the eigenvalues are close to one, see Figs. 1(c),(f). Concerning the graphs for p > 2, we can 165 see that for  $\varepsilon < 1$  the eigenvalues are close to zero as  $r^2 \to 0$ , and are increasing rapidly as  $r^2 \to 1$ , see 166 Figs. 1(g),(h). On the other hand, for  $\varepsilon = 1$  the eigenvalues are greater than one for all  $r^2$  values, see 167 Fig. 1(i). 168

REMARK 3.1. For simplicity the analysis above has been presented in  $\mathbb{R}^2$ . It can be easily extended to  $\mathbb{R}^{N_h}$ , where  $N_h$  is the dimension of  $V_{D,h}^{(k)}$ .

**3.2. The nonlinear algebraic system.** Let  $N_h$  be the dimension of the space  $V_{D,h}^{(k)}$  and  $\{\phi_{h,i}\}_{i=1}^{N_h}$  are the basis functions of  $V_{D,h}^{(k)}$ . The solution  $u_h \in V_{D,h}^{(k)}$  of problem (2.22) is expressed as  $u_h = \sum_{i}^{N_h} U_i \phi_{h,i}(x)$  where  $U_i$  are the degrees of freedom. When this expression is substituted into (2.22), we obtain the following nonlinear algebraic problem: Find the vector  $\mathbf{U} = [U_1, ..., U_i, ..., U_{N_h}]$  which satisfies the system of  $N_h$  nonlinear equations

$$\mathbf{B}(\mathbf{U}) = \mathbf{f},$$

where the entries  $B_i(\mathbf{U})$  of **B** and and  $f_i$  of **f** are specified by (2.5a), i.e.,

(3.5) 
$$B_i(\mathbf{U}) = B(u_h, \phi_{h,i}), \text{ and } f_i = l_f(\phi_{h,i}).$$

FIG. 1. Eigenvalues  $\lambda_1, \lambda_2$  of  $J_{\mathbf{A}}$ : (a) plots for  $\varepsilon = 0.001$  and p = 1.1, (b) plots for  $\varepsilon = 0.01$  and p = 1.1, (c) plots for  $\varepsilon = 1$  and p = 1.1, (d) plots for  $\varepsilon = 0.001$  and p = 1.5, (e) plots for  $\varepsilon = 0.01$  and p = 1.5, (f) plots for  $\varepsilon = 1$  and p = 1.5, (g) plots for  $\varepsilon = 0.001$  and p = 11, (h) plots for  $\varepsilon = 0.01$  and p = 11, (i) plots for  $\varepsilon = 1$  and p = 1.5, (g)

The nonlinear system (3.4) is generally large-sized and hence it is important to develop efficient iterative methods for its numerical solution, [37]. Also, it is important to investigate the influence of the parameters p and  $\varepsilon$  with respect to the convergence speed of the nonlinear iterative procedure.

Throughout this section,  $\mathbf{U}^*$  will denote the exact solution of (3.4) and  $\mathbf{U}^n$  the solution derived at step n of the iterative procedure. Furthermore  $\|.\|$  will denote the  $l^2$ -norm as well the induced matrix norm. Recall that the condition number of a matrix A relative to the norm  $\|.\|$  is given by  $\kappa(A) = \|A\| \|A^{-1}\|$ . We denote the set of eigenvalues of A by  $\sigma(A)$  and  $\rho(A) = \max_{\lambda \in \sigma(A)} |\lambda|$  is the the spectral radius of A.

# <sup>178</sup> **3.3. Newton-like methods.**

**3.3.1. Definition and algorithms..** In this subsection, we present two Newton techniques for solving (3.4). Let  $v_h = \sum_{i=1}^{N_h} V_i \phi_{h,i}$  to be an element in  $V_{D,h}^{(k)}$  with  $\mathbf{V} = [V_1, ..., V_i, ..., V_{N_h}]$ . Using (2.8) we define

(3.6) 
$$\mathbf{B}'(\mathbf{V})_{j,i} := B'(v_h)(\phi_{h,i}, \phi_{h,j}), \ i, j = 1, ..., N_h,$$

to be the iterative matrix of Newton's method. Then the main steps of a Newton method (in a matrix-vector
 form) can described as follows:

ALGORITHM 3.1 (Newton's method as defect-correction scheme). Choose an initial Newton guess  $\mathbf{U}^0$ : 1. For  $n = 0, 1, 2, ..., n_{max}$  compute the solution  $\mathbf{Z}^n$  from

(3.7a) 
$$\mathbf{B}'(\mathbf{U}^n)\mathbf{Z}^n = -(\mathbf{B}(\mathbf{U}^n) - \mathbf{f}),$$
  
Determine  $\lambda_n \in (0, 1], (e.g., see Algorithm 3.2)$   
(3.7b)  $Update: \mathbf{U}^{n+1} = \mathbf{U}^n + \lambda_n \mathbf{Z}^n.$ 

2. If the stopping criterion (see below either (3.8) or (3.9)) is satisfied then exit and set  $\mathbf{U}^* := \mathbf{U}^{n+1}$ . Otherwise repeat 1.

Usually the stopping criterion is related to a control of the magnitude of the residual of the new iteration  $\mathbf{U}^{n+1}$ , i.e,

(3.8) 
$$res_{n+1} := \|\mathbf{B}(\mathbf{U}^{n+1}) - \mathbf{f}\| \le TOL,$$

where  $TOL \sim 10^{-12}$ . Based on that we determine the parameter  $\lambda_n$  for the updating step (3.7b). However, in the literature, see e.g. [29, 37], more sophisticated Newton methods have been proposed, where the stopping criterion, the damping parameter and the updating step are determined by estimating the magnitude of the norms

(3.9) 
$$\|\mathbf{Z}^n\| \leq TOL, \text{ or } \|\mathbf{Z}_{simp}^{n+1}\| \leq TOL,$$

where  $\mathbf{Z}_{simp}^{n+1}$  is a Newton update from solving a simplified problem, see below (3.12).

Thus, we formulate two different Newton procedures, (i) a residual-based line-search procedure, which is related to the first case (3.8); see Algorithm 3.2. And (ii) an error-oriented Newton procedure, which is related to second case (3.9); see Algorithm 3.3.

ALGORITHM 3.2 (Residual-based line-search). In this procedure,  $\lambda_n$  is specified by a direct decreasing of the residual in each n-step:

190 1. Set 
$$\lambda_{n,l=0} := \lambda_{initial} = 1$$

<sup>191</sup> 2. For  $l = 0, ..., l_M$ , compute  $\mathbf{Z}^n$  by (3.7a) and update  $\mathbf{U}^{n+1,l} = \mathbf{U}^n + \lambda_{n,l} \mathbf{Z}^n$ 

192 3. Evaluate  $res_{n,l+1}$ ,

<sup>193</sup> 4. If  $res_{n,l+1} \leq res_{n,l}$  then solution found  $\mathbf{U}^{n+1} := \mathbf{U}^{n+1,l}$ ,

otherwise go to step 2, setting  $\lambda_{n,l+1} = \frac{\lambda_{n,l}}{2}$ ,

195 5. If  $l + 1 > l_M$  stop. Convergence failure.

ALGORITHM 3.3 (Error-oriented Newton's method). This procedure is based on a natural monotonicity test, i.e.,  $\|\mathbf{Z}_{simp}^{n+1}\| < \|\mathbf{Z}^{n}\|$ .

1. Choose an initial guess  $\mathbf{U}^0$ . Set the minimal damping factor, e.g.,  $\lambda_{min} \sim 10^{-8}$  and  $\lambda_0 < 1$ . For  $n = 0, 1, 2, 3, \ldots$ :

2. Solve

$$\mathbf{B}'(\mathbf{U}^n)\mathbf{Z}^n = -(\mathbf{B}(\mathbf{U}^n) - \mathbf{f}), \quad (see Newton step (3.7a)).$$

If  $\|\mathbf{Z}^n\| \leq TOL$  then the solution found and set

$$\mathbf{U}^* := \mathbf{U}^n + \mathbf{Z}^n.$$

3. If  $\|\mathbf{Z}^n\| > TOL$ , then take  $\mathbf{Z}^n_{simp}$ , which has been already computed in the previous Newton step n-1 via (3.12). Determine a new prediction value  $\lambda_n$  for the damping factor as follows:

$$\lambda_n := \min(1, \mu_n), \quad where \quad \mu_n := \frac{\|\mathbf{Z}^{n-1}\| \cdot \|\mathbf{Z}^n_{simp}\|}{\|\mathbf{Z}^n_{simp} - \mathbf{Z}^n\| \cdot \|\mathbf{Z}^n\|}$$

If

$$(3.10) \qquad \qquad \lambda_n < \lambda_{min}$$

then stop. Convergence failure and abort computation.

4. If  $\lambda_n > \lambda_{min}$  continue and compute trial iterate

$$\mathbf{U}^{n+1} := \mathbf{U}^n + \lambda_n \mathbf{Z}^n$$

and evaluate the new residual  $-(\mathbf{B}(\mathbf{U}^{n+1}) - \mathbf{f})$ . Solve the simplified linear system using the old Jacobian and the new residual

(3.12) 
$$\mathbf{B}'(\mathbf{U}^n)\mathbf{Z}_{simp}^{n+1} = -\left(\mathbf{B}(\mathbf{U}^{n+1}) - \mathbf{f}\right)$$

181

182

183

200

5. Compute the monitoring functions:

$$\theta_n := \frac{\|\mathbf{Z}_{simp}^{n+1}\|}{\|\mathbf{Z}^n\|}, \quad \mu'_n := \frac{0.5\|\mathbf{Z}^n\|\,\lambda_n^2}{\|\mathbf{Z}_{simp}^{n+1} - (1-\lambda_n)\mathbf{Z}^n\|}$$

6. If  $\theta_n \geq 1$  (no convergence of the updates), then set

$$\lambda_n := \lambda'_n := \min(\mu'_n, \frac{1}{2}\lambda_n)$$

and go to (3.10) and continue from there.

202 7. Else, if  $\theta_n < 1$ , we have convergence and continue with the next steps.

203 Set  $\lambda'_n := \min(1, \mu'_n).$ 

(a) If  $\lambda'_n = \lambda_n = 1$  then: if  $\|\mathbf{Z}_{simp}^{n+1}\| \leq TOL$  stop and the solution is found:

$$\mathbf{U}^* := \mathbf{U}^{n+1} + \mathbf{Z}^{n+1}_{simn},$$

otherwise go to the beginning to Step 2 and increment  $n \to n+1$ .

(b) If  $\lambda'_n \neq \lambda_n < 1$  go to the beginning to Step 2 and increment  $n \to n+1$ .

REMARK 3.2 (Motivation of Step 3 and Step 5). In the above algorithm, the important steps are No. 3 and 5. Both are based on adaptive trust region strategies as derived in [29], Section 3.3.3. Specifically, Step 3 is a prediction strategy that is based on a estimate of the simplified update and the full Newton update, while

<sup>209</sup> using Lipschitz continuity of the Jacobian. Step 5, is a correction strategy that is based on a damped Newton <sup>210</sup> iteration.

We underline that for finding the numerical solution  $\mathbf{U}^*$  the generated global error includes two parts, one coming form the FE discretization and the second coming by the Newton iterative procedure. Recalling (2.33) and the stopping criterion in the Newton algorithms, we can practically express the global error as

(3.13) 
$$\|\mathbf{F}(\nabla u) - \mathbf{F}(\nabla u_{h,n})\| \lesssim \mathcal{O}(h^{l-1}) + res_n,$$

where  $res_n$  is the residual at the last *n*-th Newton iteration step. Thus, the Newton iterations must be continued until the discretization error component dominates.

REMARK 3.3. In view of Jacobian  $J_{\mathbf{A}}$  defined in (3.2), the entries of iterative matrix in (3.6) are equal to  $\mathbf{B}'(\mathbf{V})_{j,i} = \int_{\Omega} J_{\mathbf{A}}(\nabla v_h) \nabla \phi_{h,i} \nabla \phi_{h,j} dx$  and consequently Newton's step in (3.7a) can be expressed as: Find  $z_h \in V_{D,h}^{(k)}$  such that

(3.14) 
$$\int_{\Omega} J_{\mathbf{A}}(\nabla u_h^n) \nabla z_h \cdot \nabla \phi_h \, dx = -\Big(\int_{\Omega} \mathbf{A}(\nabla u_h^n) \cdot \nabla \phi_h \, dx - \int_{\Omega} f \phi_h \, dx\Big), \quad \phi_h \in V_{0,h}^{(k)},$$

<sup>213</sup> where  $u_h^n \in V_{D,h}^{(k)}$  is the updated numerical solution of the previous step.

**3.3.2. Remarks on the properties for the condition number of B'.** In practice we can check the well-conditioned status of system (3.4) (and also (3.7a)) through the condition number. The condition number  $\kappa(\mathbf{B}')$  is a measure of sensitivity of the solution to relative small perturbations of the system, e.g., finite precision arithmetic, as well as a measure of the distance from a singular matrix. Roughly speaking an almost singular matrix is expected to have a large condition number and thus we expect to meet problems during the solution of the system. In our studies this could be the case where p > 2 and  $\varepsilon \to 0$ , see Figs. 1(g),(h). Next, we quote a Lemma related to inverse estimates for  $\phi_h \in V_{D,h}^{(k)}$ .

LEMMA 3.1. Let  $\phi_h = \sum_{i=1}^{N_h} v_i \phi_{h,i}$  and  $\mathbf{v} = (v_1, ..., v_{N_h})$ . There exist positive constants  $C_0$ ,  $C_m$  and  $C_M$  depending only on the quasi-uniform properties of the meshes and on k, such that

(3.15a) 
$$\|\nabla \phi_h\|_{L^2(\Omega)} \le C_0 h^{-1} \|\phi_h\|_{L^2(\Omega)},$$

(3.15b) 
$$C_m h \|\mathbf{v}\| \le \|\phi_h\|_{L^2(\Omega)} \le C_M h \|\mathbf{v}\|,$$

221 where  $\|\mathbf{v}\|^2 = v_1^2 + \ldots + v_{N_h}^2$ .

*Proof.* Both relations can be shown by applying scaling arguments, see details in [28].  $\Box$ Based on (2.8), we can clearly see that the matrix **B**' defined in (3.6) is symmetric and is positive definite. Indeed by (3.6) and (2.8), we have

(3.16)  
$$B'(u_h)(w_h, w_h) = \int_{\Omega} (\varepsilon^2 + |\nabla u_h|^2)^{\frac{p-2}{2}} |\nabla w_h|^2 dx + (p-2) \int_{\Omega} (\varepsilon^2 + |\nabla u_h|^2)^{\frac{p-4}{2}} (\nabla u_h, \nabla w_h)^2 dx.$$

205

Now, let us try to derive bounds for  $\frac{B'(u_h)(w_h,w_h)}{\|\mathbf{w}\|^2}$ . As a result, using that  $(a^2 + \beta^2) \leq (a + \beta)^2 \leq 2(a^2 + \beta^2)$  for  $a, \beta > 0$ , we have that

(3.17)  

$$B'(u_{h})(w_{h},w_{h}) \leq \int_{\Omega} (\varepsilon^{2} + |\nabla u_{h}|^{2})^{\frac{p-2}{2}} |\nabla w_{h}|^{2} dx$$

$$+|p-2| \int_{\Omega} (\varepsilon^{2} + |\nabla u_{h}|^{2})^{\frac{p-4}{2}} (\varepsilon^{2} + |\nabla u_{h}|^{2}) |\nabla w_{h}|^{2} dx$$

$$\leq C(p) \int_{\Omega} (\varepsilon^{2} + |\nabla u_{h}|^{2})^{\frac{p-2}{2}} |\nabla w_{h}|^{2} dx.$$

If p > 2 we get immediately that

(3.18) 
$$B'(u_h)(w_h, w_h) \ge \int_{\Omega} (\varepsilon^2 + |\nabla u_h|^2)^{\frac{p-2}{2}} |\nabla w_h|^2 \, dx.$$

For the case 1 , a simple modification of the last term in (3.16) yields

$$B'(u_h)(w_h, w_h) \ge \int_{\Omega} (\varepsilon^2 + |\nabla u_h|^2)^{\frac{p-2}{2}} |\nabla w_h|^2 dx$$

$$+(p-2) \int_{\Omega} (\varepsilon^2 + |\nabla u_h|^2)^{\frac{p-4}{2}} |\nabla u_h|^2 |\nabla w_h|^2 dx$$

$$\ge (p-1) \int_{\Omega} (\varepsilon^2 + |\nabla u_h|^2)^{\frac{p-2}{2}} |\nabla w_h|^2 dx$$

$$> 0$$

In the following, inspired by [31], we try to derive estimates for the condition number  $\kappa(\mathbf{B}')$ . PROPOSITION 3.2. The condition number  $\kappa(\mathbf{B}')$  can be estimated by

(3.20) 
$$\kappa(\mathbf{B}') = \frac{\lambda_{Max}}{\lambda_{min}} \le \begin{cases} C(\varepsilon + |\nabla u_h|_{\infty})^{p-2} \varepsilon^{2-p} h^{-2} & \text{for } p > 2, \\ C(\varepsilon + |\nabla u_h|_{\infty})^{2-p} \varepsilon^{p-2} h^{-2} & \text{for } 1$$

where  $\lambda_{Max}$  and  $\lambda_{min}$  are the largest and the smallest eigenvalue of **B**' respectively. *Proof.* For p > 2, it follows from (3.17) and (3.15) that

$$(3.21) \quad \frac{B'(u_h)(w_h, w_h)}{\|\mathbf{w}\|^2} \le C(\varepsilon + \|\nabla u_h\|_{\infty})^{p-2} \frac{|\nabla w_h|^2_{L^2(\Omega)}}{h^{-2} \|w_h\|^2_{L^2(\Omega)}} \le C(\varepsilon + \|\nabla u_h\|_{\infty})^{p-2} \frac{h^{-2} \|w_h\|^2_{L^2(\Omega)}}{h^{-2} \|w_h\|^2_{L^2(\Omega)}} \le C(\varepsilon + \|\nabla u_h\|_{\infty})^{p-2} \frac{|\nabla w_h|^2_{L^2(\Omega)}}{h^{-2} \|w_h\|^2_{L^2(\Omega)}} \le C(\varepsilon + \|\nabla u_h\|_{\infty})^{p-2}$$

For p > 2 using (3.18) and (2.9b), we obtain

$$(3.22) \quad \frac{B'(u_h)(w_h, w_h)}{\|\mathbf{w}\|^2} \geq C\varepsilon^{p-2} \frac{|\nabla w_h|^2_{L^2(\Omega)}}{h^{-2} \|w_h\|^2_{L^2(\Omega)}} \geq C\varepsilon^{p-2} \frac{\|w_h\|^2_{L^2(\Omega)}}{h^{-2} \|w_h\|^2_{L^2(\Omega)}} \geq C\varepsilon^{p-2} h^2.$$

On the other hand for 1 we have

$$(3.23) \quad \frac{B'(u_h)(w_h, w_h)}{\|\mathbf{w}\|^2} \leq C\varepsilon^{p-2} \frac{|\nabla w_h|^2_{L^2(\Omega)}}{h^{-2} \|w_h\|^2_{L^2(\Omega)}} \leq C\varepsilon^{p-2} \frac{h^{-2} \|w_h\|^2_{L^2(\Omega)}}{h^{-2} \|w_h\|^2_{L^2(\Omega)}} \leq C\varepsilon^{p-2}.$$

Also, for 1 using (3.19) and (2.9b), we obtain

$$(3.24) \quad \frac{B'(u_h)(w_h, w_h)}{\|\mathbf{w}\|^2} \ge C(\varepsilon + \|\nabla u_h\|_{\infty})^{p-2} \frac{|\nabla w_h|^2_{L^2(\Omega)}}{h^{-2} \|w_h\|^2_{L^2(\Omega)}} \ge C(\varepsilon + \|\nabla u_h\|_{\infty})^{p-2} \frac{\|w_h\|^2_{L^2(\Omega)}}{h^{-2} \|w_h\|^2_{L^2(\Omega)}} \ge C(\varepsilon + |\nabla u_h|_{\infty})^{p-2} h^2.$$

<sup>224</sup> Gathering together all the previous inequalities we can show (3.20).  $\Box$ 

REMARK 3.4. We note that a necessary condition for obtaining the solution  $\mathbf{Z}^n$  during the Newton 225 process, is that the iterative matrix  $\mathbf{B}'$  is invertible, see Algorithm 3.1. In the proofs of the convergence of 226 Newton's methods that have been presented in the literature, the existence of  $\mathbf{B}'^{-1}$  (at least in a neighborhood 227 of  $\mathbf{U}^*$ ) is usually supposed. Additional assumptions are the existence of  $\beta_m > 0$  and  $\beta_M > 0$  such that 228  $\beta_m \leq \|\mathbf{B}'(\mathbf{V})^{-1}\| \leq \beta_M$ . Usually, the bound  $\beta_M$  is used to define the radius of the area around  $\mathbf{U}^*$  for 229 choosing the initial  $\mathbf{U}^0$ , in order to be possible to show analytically the convergence of the method, see [29], 230 [37]. From (3.20) and (3.3), one sees that for our case it is difficult to find uniform bounds with respect to 231  $\varepsilon$  and p. In the numerical examples, we observed that, indeed the choice of  $\mathbf{U}^0$  influences the performance 232 of the Newton solver. Choosing as initial guess to be the projection of the previous mesh solution, we have a 233 fast convergence of the iterative procedure, see for instance Table 2 of Example 1. 234

TABLE 1 The steps of the two ALG1 algorithms.

**3.4.** Augmented Lagrangian techniques. In the following two paragraphs, we transform the original problem (2.1) into a saddle-point problem using augmented Lagrangian techniques. Let q be the conjugate exponent of p, that is  $\frac{1}{p} + \frac{1}{q} = 1$ , and let us define the space  $W \subset W_D^{1,p} \times (L^p(\Omega))^2$  by

(3.25) 
$$W = \{ (v, \mathbf{q}) | (v, \mathbf{q}) \in W_D^{1, p} \times (L^p(\Omega))^2 : \nabla v - \mathbf{q} = 0 \}$$

Following [38], we introduce the augmented Lagrangian  $\mathcal{L}_{\hat{r}}$  defined, for  $\hat{r} > 0$ , by

$$(3.26) \quad \mathcal{L}_{\widehat{r}}(v,\mathbf{q},\lambda) = \frac{1}{p} \int_{\Omega} (\varepsilon^2 + |\mathbf{q}|^2)^{\frac{p}{2}} dx - \int_{\Omega} f v \, dx + \frac{\widehat{r}}{2} \int_{\Omega} |\nabla v - \mathbf{q}|^2 \, dx + \int_{\Omega} \lambda \cdot (\nabla v - \mathbf{q}) \, dx,$$

and the following associated to (3.26) saddle-point problem:

(3.27a) Find{
$$u, \mathbf{q}, \lambda$$
}  $\in W_D^{1,p} \times (L^p(\Omega))^2 \times (L^q(\Omega))^2$  such that

(3.27b) 
$$\mathcal{L}_{\widehat{r}}(u, \mathbf{q}, \mu) \leq \mathcal{L}_{\widehat{r}}(u, \mathbf{q}, \lambda) \leq \mathcal{L}_{\widehat{r}}(v, \mathbf{w}, \lambda),$$

(3.27c) 
$$\forall \{v, \mathbf{w}, \mu\} \in W_D^{1, p} \times (L^p(\Omega))^2 \times (L^q(\Omega))^2.$$

In that way, we reduce the solution of (2.1) to finding the saddle-point solutions of  $\mathcal{L}_{\hat{r}}$ . We apply a variational 235 analysis to (3.27) and then for computing the saddle point solutions, we employ two variants of the first 236 augmented Lagrangian iterative algorithm, (ALG1), described in [32]. The two algorithms are listed in Table 237 1, where  $0 < \hat{\rho} < 2\hat{r}$ . In the first case the Lagrangian  $\lambda$  is updated separately by applying a post-processing 238 procedure at the end of every iterative circle, which has been previously performed for computing  $u, \mathbf{q}$ . We 239 call the first version as splitting ALG1, (sALG1), and we present the algorithm on the left column in Table 240 1. In the second iterative ALG1 procedure, all the unknowns are simultaneously computed at every step, 241 and we call this procedure as monolithic ALG1, (mALG1). The algorithm of the mALG1 iterative method 242 is given on the right column in Table 1. The analysis for showing the existence and uniqueness of the saddle 243 point problems seems to be quite hard, and as well the study of the convergence properties of the resulting 244 ALG methods. Such results are discussed in [32] for several problems set in  $W^{2,2}$ 245

At first glance the ALG1 technique seems not to be so attractive due to the introduction of the two variables  $\mathbf{q}$  and  $\lambda$ . But as we can see from Table 1, the ALG1 method helps us to simplify the nonlinear structure of the original problem. In particular we are able to uncouple the strong nonlinearity of the model and the derivatives of u. The convergence properties of algorithm sALG1 have been studied in [32] for  $\hat{r} > 0$ . Recalling the finite dimensional spaces defined in (2.13), the discrete variational form of the sALG1 method has as follows: for  $\lambda_h^0$  given, find  $(u_h^i, \mathbf{q}_h^i)$  such that

(3.28a) 
$$\widehat{r}(\nabla u_h^{i,n}, \nabla v_h) + (\widehat{r} \nabla \cdot \mathbf{q}_h^{i,n}, v_h) = (\nabla \cdot \lambda_h^i + f, v_h), \quad \forall v_h \in V_{0,h}^{(k)},$$

(3.28b) 
$$((\varepsilon^2 + |\mathbf{q}_h^{i,n}|^2)^{\frac{p-2}{2}} \mathbf{q}_h^{i,n}, \phi_h) - \widehat{r}(\nabla u_h^{i,n} - \mathbf{q}_h^{i,n}, \phi_h) = (\lambda_h^i, \phi_h), \quad \forall \phi_h \in (V_h^{(k)})^2,$$

(3.28c) Update: 
$$\lambda_h^{i+1} = \lambda_h^i + \widehat{\rho}(\nabla u_h^{i,n_M} - \mathbf{q}_h^{i,n_M}).$$

Following a standard FE methodology, as in Section 3.2, we obtain the following nonlinear algebraic system

(3.29) 
$$\mathbf{B}_{sALG1}\begin{pmatrix}\mathbf{U}\\\mathbf{Q}\end{pmatrix} = \mathbf{f}_{sALG1},$$

where **U** and **Q** are the vectors with the degrees of freedom of  $u_h^{i,n}$  and  $\mathbf{q}_h^{i,n}$  respectively. A similar discrete variational form can be derived for the mALG1 method and then we get the following nonlinear algebraic system

(3.30) 
$$\mathbf{B}_{mALG1}\begin{pmatrix}\mathbf{U}\\\mathbf{Q}\\\mathbf{\Lambda}\end{pmatrix} = \mathbf{f}_{mALG1},$$

where **U**, **Q** and **A** are the vectors with the degrees of freedom of  $u_h^n$  and  $\mathbf{q}_h^n$  and  $\lambda_h^n$  respectively.

REMARK 3.5. The resulting nonlinear algebraic systems (3.29) and (3.30) can be solved by utilizing any of the two Newton variants, see Algorithm 3.2 and Algorithm 3.3. In the numerical examples, we use Algorithm 3.2 where the stopping criterion is defined in an analogous way as in (3.8). In particular, the stopping criterion for the augmented Lagrangian iterative loop in sALG1 is defined as

$$\max\{\|\mathbf{U}^{i+1} - \mathbf{U}^{i}\|, \|\mathbf{Q}^{i+1} - \mathbf{Q}^{i}\|, \|\mathbf{\Lambda}^{i+1} - \mathbf{\Lambda}^{i}\|\} \le 10^{-6}.$$

REMARK 3.6. We notice that all linear equation systems in this paper are solved with the direct solver UMPACK [39]. We are currently working on developing iterative solvers based on geometric multigrid.

REMARK 3.7. In the numerical examples, the parameters  $\hat{r}$  and  $\hat{\rho}$  have been specified after carrying out few computations using different values. As outlined in [32], the optimal choice for  $\hat{r}$  is an open question. Through the performance of the numerical tests, we have observed that the method sALG1 is more sensitive to the choice of  $\hat{r}$  than the mALG1. The mALG1 method appears to have greater robustness on the choice of  $\hat{r}$  and  $\hat{\rho}$  with respect to p. In the numerical examples, we have used  $\hat{\rho} = \hat{r} = 1$  for sALG1 and  $\hat{r} = 100$ ,  $\hat{\rho} = 0.1$  for mALG1. Choosing this high value for  $\hat{r}$ , in fact we increase the strength of the penalization in the mALG1 method.

4. Numerical examples. In this section, we perform several numerical tests by selecting different 257 values for the exponent p and investigate the order of accuracy of the proposed FE method. We mainly 258 focus on cases where 1 but do also consider a few tests with <math>p > 2. The examples have been 259 performed using first (k = 1) and second order (k = 2) polynomial spaces. We compare the error convergence 260 rates versus the grid size for several values of  $\varepsilon$  ranging between 10<sup>-4</sup> and 1. Each example has been 261 solve applying several mesh refinement steps with  $h_i, h_{i+1}, ...,$  satisfying Assumption 2.3. The numerical convergence rates r have been computed by the ratio  $r = \frac{\ln(e_i/e_{i+1})}{\ln(h_i/h_{i+1})}, i = 1, 2, ...,$  where the corresponding 262 263 error is  $e_i := \|\mathbf{F}(\nabla u) - \mathbf{F}(\nabla u_{h,n})\|_{L^2}$ , see (2.33), and  $u_{h,n}$  is the final solution computed by the iterative 264 procedure. We mention that, in the test cases with smooth solutions, i.e.,  $k+1 \leq l$ , the approximation 265 order in (2.33) is expected to be equal to k. The column in the tables below which are related to N indicate 266 the maximum number of the nonlinear iterative steps. All tests have been performed with the C++ library 267 deal.II [35, 36] using an Intel(R) Core(TM) i5-3320M CPU 2.60GHz computer. 268

# 4.1. Newton like methods.

247

Example 1,  $(|\nabla u| \neq 0, \forall x \in \Omega)$ . The first numerical example is a simple test case for validating the error estimates given in Theorem 2.7 and demonstrating the performance of the Newton method for several values of  $\varepsilon$ . We take  $\Omega \subset \mathbb{R}^2$  to be the square domain  $(0, \frac{\pi}{2})^2$ . The boundary data  $u_D$  and the function f in (2.1), are chosen so that the exact solution in (2.1) to be  $u(x, y) = \sin(x)$ . The exact solution is shown in Fig. 2 and it holds  $\{x \in \Omega : \nabla u = 0\} = \emptyset$ .

FIG. 2. Example 1: Display of the numerical solution for the case p = 1.01 and  $\varepsilon = 1.0e - 4$ .

We compute numerically the convergence rates of the error on a sequence of successively refined meshes and also we investigate the performance of the residual-based Newton method for different choices of  $\varepsilon$ . Here we consider two different choices for the starting solution  $u_h^0$  for Newton methods, (i) we set  $u_h^0 = 0$ , (ii)  $u_h^0 = Proj(u_{2h}^n)$ , where  $Proj(u_{2h}^n)$  is the projection of the solution  $u_{2h}^n$ , which has been computed on the previous space  $V_{D,2h}^{(k)}$ , to the current space  $V_{D,h}^{(k)}$ . Here the index *n* denotes the last (i.e., converged) solution on the coarser space  $V_{D,2h}^{(k)}$ . The projection is carried out as nodal interpolation from the coarse mesh on the finer mesh.

In Table 2, we display the results for polynomial degree k = 1, for p = 1.01 and for  $\varepsilon = 10^{-3}$  (right 282 columns) and  $\varepsilon = 10^{-4}$  (left columns). For both  $\varepsilon$  cases, we observe that the rates r related to the first 283 coarse meshes are little less than the expected rates, but progressively as the mesh is refined, the rates tend 284 to the optimal value r = 1, which is in agreement with Theorem 2.7. For the case  $u_h^0 = 0$ , we observe that 285 the Newton method is not mesh independent in the sense that the number of the steps is not stable as the 286 mesh is further refined. On the other hand for the case  $u_h^0 = Proj(u_{2h}^n)$ , we observe mesh independence and 287 the further number of steps is significantly reduced, see also comments in Remark 3.4. For theoretical results 288 on mesh independence for general nonlinear problems we refer the reader to [40]. As expected, this behavior 289 of the Newton method affects the corresponding CPU times, which are provided on the last row of the Table 290

|         |               |      |                         | TABLE 2                     |             |      |                         |                             |

Example 1: The results for the different values of  $\varepsilon$ .

We repeat the previous computations choosing  $\varepsilon = 10^{-2}$  and  $\varepsilon = 1$ . The results are shown in Table 3. We can clearly see that the rates r are in fully agreement with Theorem 2.7. The Newton method is mesh independent and in particular for the case  $\varepsilon = 1$  only few steps (less than 3) are needed. In comparison to the corresponding data in Table 2 the CPU times are reduced in Table 3 as a result of the fewer iterative steps. By the results of the two previous numerical tests, we conclude that the rates r are very close to the expected value for all  $\varepsilon$  but the Newton steps are increased as the values of  $\varepsilon$  become smaller.

Example 1: The results for the different values of  $\varepsilon$ .

Next, we investigate the convergence rate of the error and the performance of the residual-based Newton method for p = 1.1 and for three different choices of  $\varepsilon$ . The results are shown in Table 4. Here, we can see that for each of the three values of  $\varepsilon$ , the error  $\|\mathbf{F}(\nabla u) - \mathbf{F}(\nabla u_h^n)\|_{L^2}$  converges to zero with rate r close to one, which is in agreement with Theorem 2.7. The Newton performance appears to be mesh independent. The required total steps are increased as the value of  $\varepsilon$  is decreased.

As a last computation in this example, we solve the problem using k = 2 polynomials. The parameter ptakes the limiting values p = 1.01 and p = 1.1. Again, as in the above tests, we investigate the behavior of

Example 1: The results for the different values of  $\varepsilon$ .

the convergence of the error as well the behavior of the iterative solver for several values of  $\varepsilon$ . The results are displayed in Table 5 and in Table 6. Here, we observe for  $\varepsilon = 10^{-4}$  that the error converges with the expected rate r for both p-cases. We repeat the computations setting  $\varepsilon = 0.1$ . Also, in this case the convergence rates of the error tend to obtain the optimal value r = 2 as the mesh is refined. For both p-cases, the rates are optimal for all mesh refinement levels and the iterative solver needs less than two steps for obtaining the solution. Again, this test illustrates the affection of the parameter  $\varepsilon$  to the performance of the iterative solver.

Example 1: The results for k = 2 for different choices of  $\varepsilon$ .

Example 2, (existence of  $x_0 \in \Omega$ :  $|\nabla u(x_0)| = 0$ ).

In the second example, we want to investigate the convergence rates of the error and the corresponding behavior of the residual-based Newton method in case of the presence of critical points, i.e.,  $\{x_0 \in \Omega : |\nabla u(x_0)| = 0\}$ . In this situation the iterative matrix **B'** in (3.7a) tends to become singular or ill-conditioned as  $\varepsilon \to 0$ . To this end, the domain is  $\Omega = (0, 1)^2$  and the data  $u_D$  and f are selected so that the exact solution to be given by  $u(x, y) = \sin(2\pi(x + y))$ , which is plotted in Fig. 3. Note that the solution contains critical points along the lines  $y = \frac{1}{4} - x$  and  $y = \frac{3}{4} - x$ . We solved the problem using k = 1 polynomial space and initial guess  $u_h^0 = Proj(u_{2h}^n)$ . We compute the convergence rates on a sequence of seven successively finer meshes for several values of p and  $\varepsilon$  ranging from  $10^{-4}$  to 1. In Table 7, we show the convergence rates r

FIG. 3. Example 2: Display of the solution for the case p = 1.01 and  $\varepsilon = 1.0$ .

and the Newton iterations for each selected p and each  $\varepsilon$ . The reported rate r is the minimum rate computed 320 on the last three finer meshes. The reported number of Newton iterations N, is the maximum number of 321 the Newton iterations that have been used on the three finer meshes. We can clearly see, that for p < 2322 the performance of the Newton solver is very sensitive to the choice of  $\varepsilon$ . In particular the value of  $\varepsilon$  must 323 be close to one in order to perform successfully the Newton iterative procedure. An exception is the case 324 of p = 1.8 where the problem has been solved for all values of  $\varepsilon$  using a relatively small number of iterative 325 steps N. On the other hand for the tests with p > 2, the problem has been successfully solved for all the 326 selected values of  $\varepsilon$ . We can see that the rates have the expected values and the Newton method appears to 327 have a mesh independent behavior. For the case p = 11, we observe an increase in the Newton steps without 328 having a deterioration of the convergence rates.

329

FIG. 4. Example 3: Display of the numerical solution for the case p = 1.5 and  $\varepsilon = 1.0$  and  $\gamma = 0.8$  and k = 1.

Example 3: (low-regularity solution,  $u \in W^{l,p}(\Omega)$ , l = 2 and l = 3). This example consists of a problem 330 with low regularity solution, i.e.,  $u(x,y) = (x^2 + y^2)^{\frac{\gamma}{2}}$ , for several values for the parameter  $\gamma$ , see also [17]. The 331 computational domain is the rectangle  $\Omega = (-0.5, 0.5)^2$ . The source function f and  $u_D$  are manufactured by 332 the exact solution. We point out that the regularity of the solution is specified by the value of the parameter 333  $\gamma$  and in this example, we investigate the ability of the whole method (FE discretization and Newton solver) 334 to approximate low regularity solutions of (2.1) with the expected accuracy. Thus, this example seems to 335 be quite interesting, since we can predefine the regularity of the proposed exact solution to be close to the 336 required regularity of the solution, which has been assumed in the error analysis, see Assumptions 2.1, 2.3 337

Example 3: the expected convergence rates r for the several values of the parameters  $\gamma$  and p.

and Remark 2.2. In Table 8, for several values of the parameters  $\gamma$  and p, we display the space  $W^{l,p}$  where the solution u belongs to. Also, the expected convergence rates r are mentioned. For validation, we have computed the convergence rates in all cases setting  $\varepsilon = 1$ , see Table 8. Note that in this case we have that  $\frac{1}{\tau} \in L^q(\Omega), q = \frac{p}{p-1}$ , see Assumption 2.3 and Remark 2.2. We solve the problem using k = 1 and k = 2polynomial spaces and utilizing both Newton iterative solvers, residual based-line, see Algorithm 3.2 and error-oriented, see Algorithm 3.3.

Example 3: the numerical convergence rates r and the nonlinear iterative steps N for the several values of  $\gamma$  and p.

In Table 9, we present the convergence rates r, as well the maximum number of the nonlinear iterative 344 steps. In particular, the column of  $N_{RB}$  corresponds to the steps of the residual-based method, and the 345 column of  $N_{EO}$  corresponds to the error-oriented method. In Table 9, we report only one column with 346 convergence rates r, because both Newton iterative methods yield the same result. We observe that the 347 rates related to  $\gamma = 0.72, l = 2, p = 1.5$  are slightly below the expected value r = 1, see Table 8, but 348 are progressively increased as we use finer meshes. For the p = 1.8 test case, the rates r corresponding to 349 k = 1 and k = 2 solutions are very close to the expected values. For the last p = 3 test case, the rates r 350 corresponding to k = 1 are in good agreement with Table 8, but the rates r corresponding to k = 2 are little 351 higher. Here, we would like to note that in several numerical experiments that we have performed using 352 p > 2, the numerical rates have been found to be greater than those predicted by the theory, e.g., see Tables 353 9, 10 and 12 below. Similar rate behavior has been observed in the corresponding tests presented in [17].<sup>3</sup> 354 Concerning the iterative methods, we observe that both have mesh independent and p independent 355 behavior. However, the performance of the error-oriented method needs less steps. However, this does not 356 entail into a remarkable reduction of the corresponding CPU times, see the corresponding row in Table 8. 357 The reason is that the error-oriented method is more expensive than the residual-based method, because we 358 solve the linearized system two times per step; see Algorithm 3.3. Continuing with the results for l = 3 that 359

<sup>&</sup>lt;sup>3</sup>For a further investigation, we have performed more computations using different values for  $\gamma$  and p. Again, in some cases, we found little higher rates than the rates expected by the theory.

4.2. Augmented Lagrangian methods. In this paragraph we present two numerical examples that have been solved using the two ALG1 variants, see Table 1 in Section 3.4. Concretely, we have solved the same problems as in Example 2 and in Example 3 in order to compare the residual-based Newton method with the two ALG1 approaches.

Example 4: (existence of  $x_0 \in \Omega$ :  $|\nabla u(x_0)| = 0$ ). We set  $\Omega = (0,1)^2$  and the boundary data  $u_D$  and f 370 are prescribed by the exact solution  $u(x, y) = \sin(2\pi(x+y))$ , see also Example 2 above. We consider six levels 371 of mesh refinement and four values for  $p \in \{1.01, 1.5, 3, 4.3\}$ . The numerical tests has been performed using 372 k=1 polynomial space and  $\varepsilon=1$ . We mention that we also performed computations using the remaining 373 values of  $\varepsilon$  in Table 7. The derived results were similar to that which are described in Table 7 and thus we 374 report only the case  $\varepsilon = 1$ . In Table 10, we show the numerical convergence rates and the corresponding 375 iterative steps that we have found for the sALG1 method. In Table 11, we show the corresponding data of 376 mALG1 method. In both tables the column associated with N indicates the number of nonlinear (Newtons) 377 iterations necessary to achieve the convergence criteria. In general, we observe that both methods sALG1 378 and mALG1 converge quite fast, as few as 2 iterations on fine meshes. In some cases, the proposed mALG1 379 method requires less steps to reach the stopping criterion, see for example the p = 1.5 case. The number N 380 of iterations remains stable and very low for the last mesh levels, thus we can say that both ALG1 methods 381 exhibit a mesh independent behavior. Also we observe that the convergence rates of sALG1 appear to be 382 383 little higher than the theory predicts. On the other hand the convergence rates r corresponding to mALG1 method are very close to the rates predicted by the theory.

TABLE 10

Example 4: sALG1 method. The convergence rates and the iterative steps for several values of p.

Example 4: mALG1 method. The convergence rates and the iterative steps for several values of p.

384

Example 5: (low regularity solution). We consider  $\Omega = (-0.5, 0.5)^2$  and the exact solution u(x, y) =385  $(x^2+y^2)^{\frac{\gamma}{2}}$ , see also Example 3, Table 8 and Table 9. We have solved the problem using linear elements k=1386 387 giving to  $\gamma$  and p the values of the second row in Table 8. We compare the two different ALG1 methods by choosing three different test cases associated with three different values for p, i.e.,  $p = \{1.5, 1.8, 3\}$ . Table 388 12 corresponds to sALG1 method and it displays the convergence rates of the error and the iterative steps 380 N for every mesh level. The results related to mALG1 method are displayed in Table 13. The initial guess 390 is defined to be the projection of the previous coarse mesh solution. We begin with the results of sALG1 391 displayed in Table 12 and are associated with l = 2 regularity. We observe that for p = 1.5 the rates, for 392 both k = 1 and k = 2 spaces, are slightly less than the expected optimal r = 1 rate, but they progressively 393 increase towards the optimal value. For the case of p = 1.8 the rates r of both numerical solutions k = 1 and 394 k=2 are very close to the optimal value r=1 which is determined by the regularity of u. On the other hand 395 the rates for p = 3 case are little higher on the first meshes but are progressively reduced. In general, the 396 convergence rates in Table 12, which are related to l = 2 regularity, are closer to the rates presented in Table 397 8, in comparison to the rates that we show in Table 9. Looking at Table 12 the column with the number of 398 the nonlinear iterative steps, we observe that in general the sALG1 method has a mesh independent behavior. 399 The iterative steps corresponding to k = 1 solutions are considerably more than the steps corresponding to 400 k = 2 solutions. This does not have an impact on the total CPU time, since we observe that the CPU time 401 of k = 2 computations is much higher that the CPU time of k = 1 computations, see the corresponding row 402 in Table 12. 403

Also, Table 12 shows the results for the l = 3 tests (see last rows). We observe that the rates related to k = 1 for all *p*-cases are little higher than the r = 1 (expected value). On the other hand the rates *r* related

Example 5: mALG1 for solving problems with low regularity solution. The numerical convergence rates and the iterative steps for the several values of  $\gamma$  and p.

to p = 1.5, k = 2 solutions are little lower than expected. For the two other p-cases, the convergence rates of 406 407 k = 2 numerical solutions are close to the expected r = 2 rate. Concerning the variations of the numbers N of the iterative steps, we observe similar behavior as in the previous l = 2 test case. More precisely, although the 408 steps of k = 1 numerical solutions are again quite higher than the steps of k = 2 solutions, the corresponding 409 CPU time of k = 1 solutions is smaller. This occurs due to the fact that ALG1 methods introduce two new 410 variables, see Table 1. Thus, when we use k = 2 spaces, the resulting algebraic linear system at each Newton 411 step, has a high number of unknowns, and therefore its solution requires much more computing time. Here, 412 advanced techniques, e.g. efficient preconditioners such as for instance multigrid techniques must be applied. 413 This is a topic that we will discuss in a forthcoming paper; see also Remark 3.6. 414

We continue with the results of mALG1 method for l = 2 regularity case, see first rows in Table 13. 415 For the p = 1.5 test case, we observe that the rates r corresponding to k = 1 solutions are little lower than 416 the optimal value but moving to finer meshes the rates are approaching the optimal value. For the other 417 two p-cases the rates of k = 1 solutions are much closer to the expected r = 1 value. Concerning the rates 418 of k=2 solutions, we can see that are close to r=1 which is not surprising since  $u \in W^{l=2,p}$ . We have 419 to remark that the rates obtained for p = 3 test case are little bit more higher than expected. Finally, we 420 mention that, for all *p*-cases, the required number of iterative steps is not increased as we use finer grids, even 421 for k = 2 spaces. This indicates that the proposed mALG1 method follows a mesh-independent behavior. 422 Here, we also observe that the number of the iterative steps for both cases k = 1 and k = 2 are very close, 423 and such a behavior did not appear in sALG1 method. Concerning the CPU times displayed in the last row, 424 similar comments as in previous tests of sALG1 method can be expressed. 425

The last rows in Table 13 show the results related to l = 3 regularity test case. We observe that for each 426 of the three p-tests the error related to k = 1 spaces convergences at the optimal rate r = 1, as predicted by 427 Theorem 2.33, see also Table 8. As in the previous examples, the error convergence rates related to k = 2428 numerical solutions is little below the expected value for the case of p = 1.5, but the rates are in agreement 429 with the predicted rates for the rest p-cases. In general, we can say that the rates behave in a similar manner 430 as in Example 3, where the residual-based method applied, see last lines in Table 8. Also, Table 13 presents 431 the actual number of the nonlinear iterative steps at every mesh. We see that the iterative steps of both 432 k = 1 and k = 2 solutions are very close. For each choice of p, the solution is obtained in very few iterative 433 steps even on the last mesh levels. Also we note that the number of the iterative steps is not increased as 434 we increase the value of p. We did not observe the same in Table 12 which shows the results for the sALG1 435 method. This fact indicates the robustness of the new proposed mALG1 method with respect the choice of 436 p. Finally, in the last row in Table 13, we can see the corresponding CPU times. As in the l = 2 case and as 437 in sALG1 method, the CPU times of k = 2 solutions are quite larger than the CPU times of k = 1 solutions. 438 This is not the case for the two Newton methods, see last row in Table 9. 439

As a final comment we can say that the two ALG1 methods appear to be quite appropriate for solving the nonlinear system in (3.4). This seems to be a result of the particular decomposition of the problem and the treatment of the nonlinear terms. On the other hand, this ALG1 decomposition introduces additional unknowns, which results in the creation of a large system.

5. Conclusions. In this article, we applied finite element methods for the numerical solution of p-power-444 law diffusion problems. Under some regularity assumptions for the exact solution we derived a priori error 445 estimates. The theoretical error estimates were demonstrated by numerical examples using several values 446 for the parameters of the problem. Next, we presented nonlinear iterative solvers. Initially, we analyzed 447 two Newton-like iterative methods, a residual-based and an error-oriented technique. We discussed in detail the condition properties of the Newton iterative matrix. Even though the error-oriented procedure finds the 449 solution in less iterations than the residual-based technique, the latter is easier to be materialized. However, in 450 the error-oriented method the linear system is solved twice, which finally makes the two methods to be appear 451 equivalent in terms of CPU time. In addition, we applied two augmented Lagrangian methodologies for solving 452 the original *p*-type elliptic problem. The resulting iterative methods can be characterized by the simplicity 453 of the algorithm and are able to provide a nice handling of the nonlinear terms via the decomposition of 454 the original problem. Nevertheless, the introduction of the additional unknowns that accompanies the ALG1 455 framework, yields a large system at each Newton step. For an efficient solution of this system, it seems that 456 we need to apply more advanced techniques, which we envisage to develop in future work. 457
